

Plan, Build, and Protect **Remotely Mapping Geology** with Naturally Sourced Electromagnetic Analysis (NSEM) a presentation by Dynamic Measurement LLC for NOD/US Army Corps of Engineers

19 December 2014

Presentation Topic Areas

- NSEM A new technology to identify geologic hazards
 Questions & Answers & Discussion
- 2. The meteorology behind lightning databases
 - Questions & Answers & Discussion
- 3. Calculating resistivity volumes from lightning databases
 Questions & Answers & Discussion
- 4. Examples of using lightning databases to map geologyQuestions & Answers & Discussion
- 5. Goose Point tectonic driven subsidence lightning case history
 Questions & Answers & Discussion

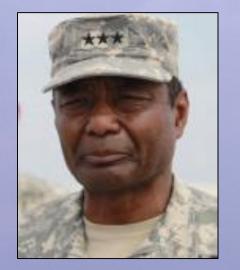

1. NSEM – A new technology to identify geologic hazards

19-Dec-14

DML will help the nation's engineers!

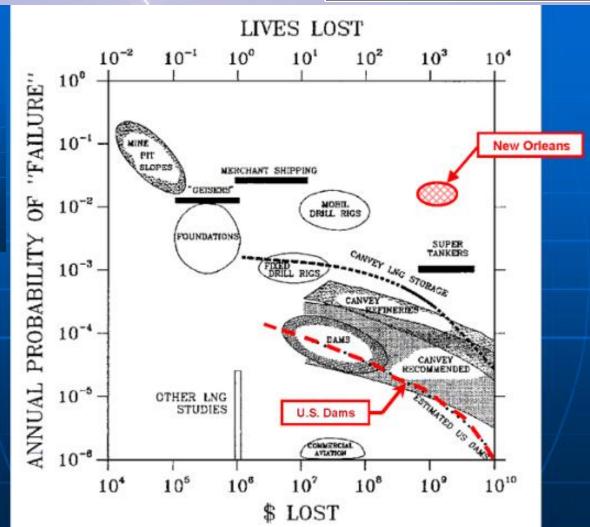

Investigation of the Performance of the New Orleans Flood Protection Systems in Hurricane Katrina

"... individual projects are at high risk."

Exclusive worldwide license with Vaisala of Finland to use their data in the NLDN and GLD-360 for natural resource exploration.

Questions & Answers & Discussion

19-Dec-14

3. Calculating resistivity volumes from lightning databases

Recorded Lightning Data

19-Dec-14

- Lightning measurements 30+ years
- Continuous record in U.S.A. and Canada 16+ years

Continuous record worldwide – 4+ years

The atmosphere is an effective insulator

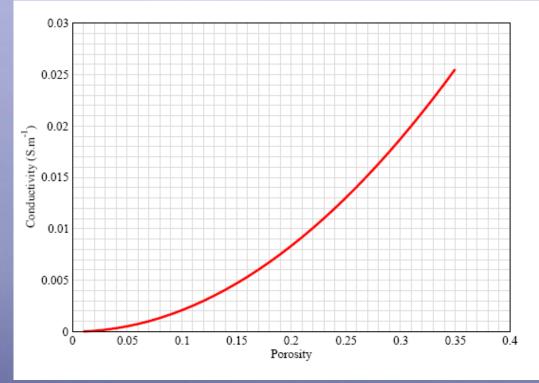

The electrical conductivity of air is 0.3-0.8 * 10⁻¹⁴ S.m⁻¹ (Siemens per meter).

> The effectiveness seen in air's common use separating high voltage transmission lines from the ground, from towers used to support the lines, and from lines carrying different voltages and different phases.

The earth is much more conductive than air

Assuming a typical sedimentary rock has 5% porosity, the electrical conductivity of rocks is 5.0 * 10⁻⁴ S.m⁻¹, or about 10¹⁰ times the conductivity of air.

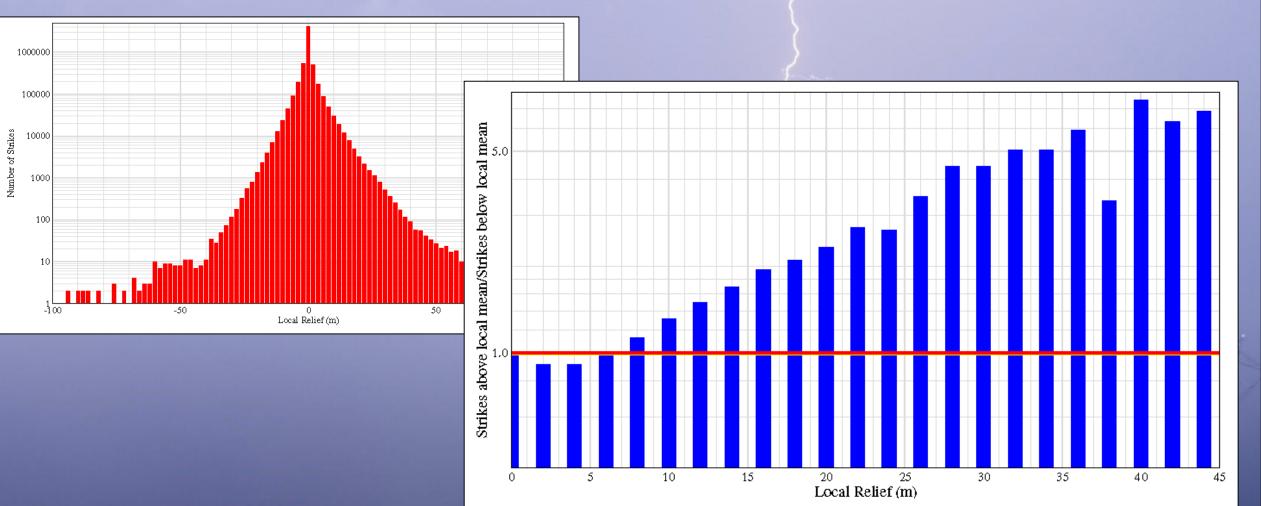

Rock Conductivity Graph computed for a porous rock with 100% brine saturation using Archie's equation

The Atmospheric Capacitor Plate 1

- The charged thundercloud is one plate of a capacitor
- The other plate of the capacitor is the earth underlying the charged cloud
- The dielectric is the air

19-Dec-14

• Energy from a lightning strike is converted to heat, partly in the air, but largely in the subsurface

Plate 2

Dielectric

Lightning a Dielectric Breakdown

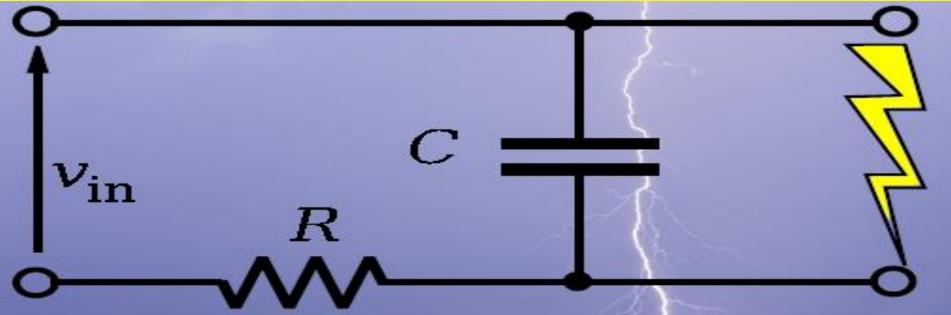

- Lightning occurs when the voltage across the atmospheric capacitor exceeds the dielectric strength of the air.
- Resistance in the atmosphere is very low once the path is ionized.
- Resistance in the subsurface is approximately constant over long periods of time.
- Atmospheric factors vary with each stroke.

See Lightning Think Dynamic Measurement LLC

Relaxation Oscillator

19-Dec-14

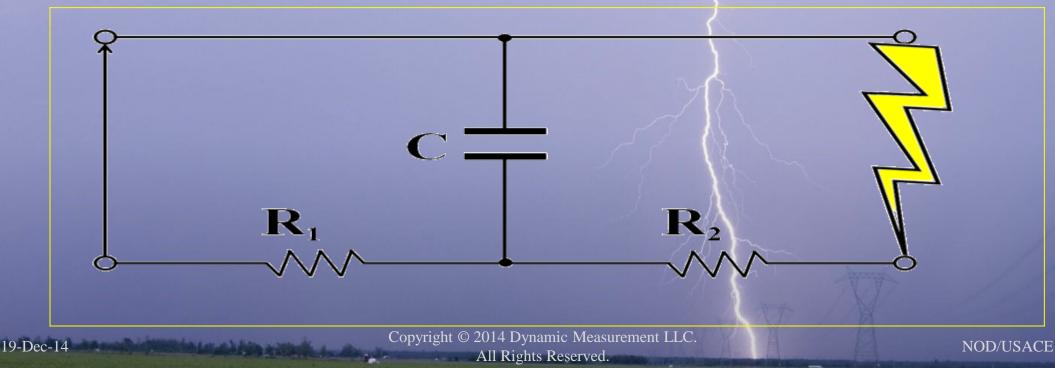

- The physics of lightning discharge are similar to the physics of a neon-tube relaxation oscillator.
- In each case, voltage builds across a capacitor until an insulating gas ionizes and becomes a conductor

Lightning Physics

- The atmospheric capacitor is nearly the same
- Just an additional resistance R₂ limiting the current
- R₂ is the resistance between the lightning strike point and the bottom plate of the capacitor

Relaxation Oscillator Physics

- When a relaxation oscillator triggers, the discharge current decays exponentially
- > The rate of decay is given by $I_t = I_0 e^{-t/RC}$
- ▶ If lightning is similar, can we use the decay to measure resistance?
 - For This equation can be rearranged to $ln(\frac{l_i}{l_0}) = -\frac{i}{RC}$ or $R = -\frac{i}{ln(\frac{l_i}{l_0})C}$.
 - All we need is the current at two times (I₀ and I₁), and the capacitance (C) to get the resistance R

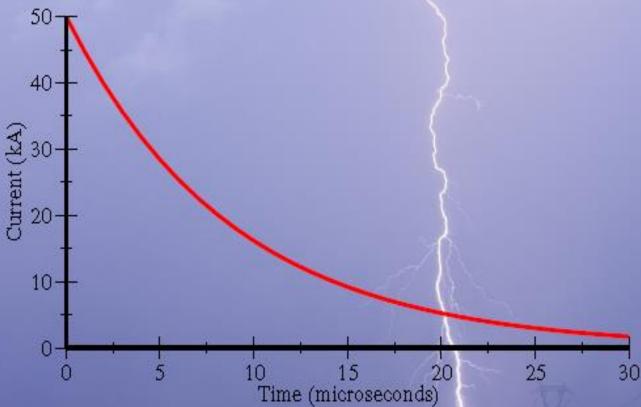

How do we measure Decay

- Lightning measurements do not give this kind of continuous decay.
- We have two values: ⁵⁰
 - Peak current

19-Dec-14

• Peak to zero time

See Lightning Think Dynamic Measurement LLC

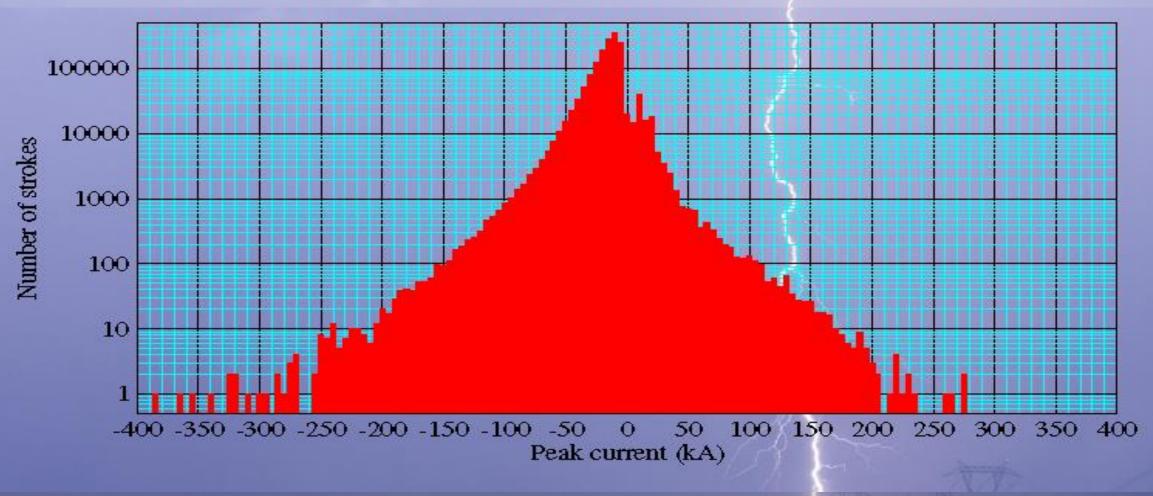

The Available Measurements

• Two points on an exponential curve will define the curve **Peak Current**:

- The maximum recorded current, when decay starts (I₀) *Peak-to-Zero time:*
- The elapsed time from the instant of Peak Current until the recorded signal disappears into the background noise.
- This gives us the time t.
- But what is the current (I_t) ?
- The time for current to decay to a real zero is infinite.
- We need an estimate of the magnitude of the "zero" current (at time *t*) in order to compute resistance.

What is Zero Current?

Total strikes 1.6 million

19-Dec-14

- 320,000 less than 10 kA absolute peak current
- 30,400 less than 5 kA absolute peak current
- 13,260 less than 4 kA absolute peak current
- 2,579 less than 3 kA absolute peak current
- 15 less than 2 kA absolute peak current
- "Zero" current assumed to be 1 kA

See Lightning Think Dynamic Measurement LLC

What About Voltage?

- Resistance is equal to voltage/current.
- Our measurements are of current only.
- But the equation gives a solution with capacitance rather than voltage.
- However, how do we find capacitance?
- Capacitance depends on permittivity, plate area, and plate separation.
- While permittivity is approximately constant and known for air, assumptions for area and separation are needed to solve for resistance.

See Lightning Think Dynamic Measurement LLC

The Assumptions

- 1. Voltage is proportional to peak current (within a local area).
- 2. Cloud height is proportional to voltage because the dielectric strength of air is more or less constant.
 - This gives plate separation for the atmospheric capacitor
- 3. The effective capacitor is circular, with a radius proportional to cloud height.
 - This gives plate area for the capacitor
- 4. With over 100 lightning strikes per square kilometer in the database in many areas, we can stack results to improve signal-to-noise ratio

What is Resistivity?

- Resistivity is resistance times cross-sectional area of a conductor, divided by its length; or $\rho = \frac{R \times A}{l}$
- ► For the lightning energy dissipating in the ground:
 - ▶ The area is very small at the strike point, but increases rapidly
 - The length is very short for discharging the charge close to the strike point, but for points near the edge of the effective capacitor, the length is much greater
- ▶ For low energy lightning, the resistivity measured is that of rocks close to the surface
- For higher energy lightning, the resistivity measured is an average of resistivities to greater depths.

Resistivity and Depth

 As mentioned above, electrical energy from more powerful strikes is partially dissipated at greater depths.

 So grouping strikes by peak current will give resistivities grouped by depth.

Determining Resistivity and Depth

- 1. Lightning data is divided into several groups (typically 10) by absolute peak current.
- 2. Each peak current group is divided into small (typically 0.03-0.04 km²) cells by latitude and longitude.
 - Not all cells will contain a lightning strike, but some cells will contain more than one lightning strike.
- 3. For each cell in each group, resistivity and depth values are computed from the lightning data.
- 4. For each group a smooth surface is fitted to the depth values and to the resistivity values.
 - At any point in the project area, a number of depth/resistivity pairs equal to the number of groups in 1 can be produced by extracting grid values at that point.

A Resistivity Trace

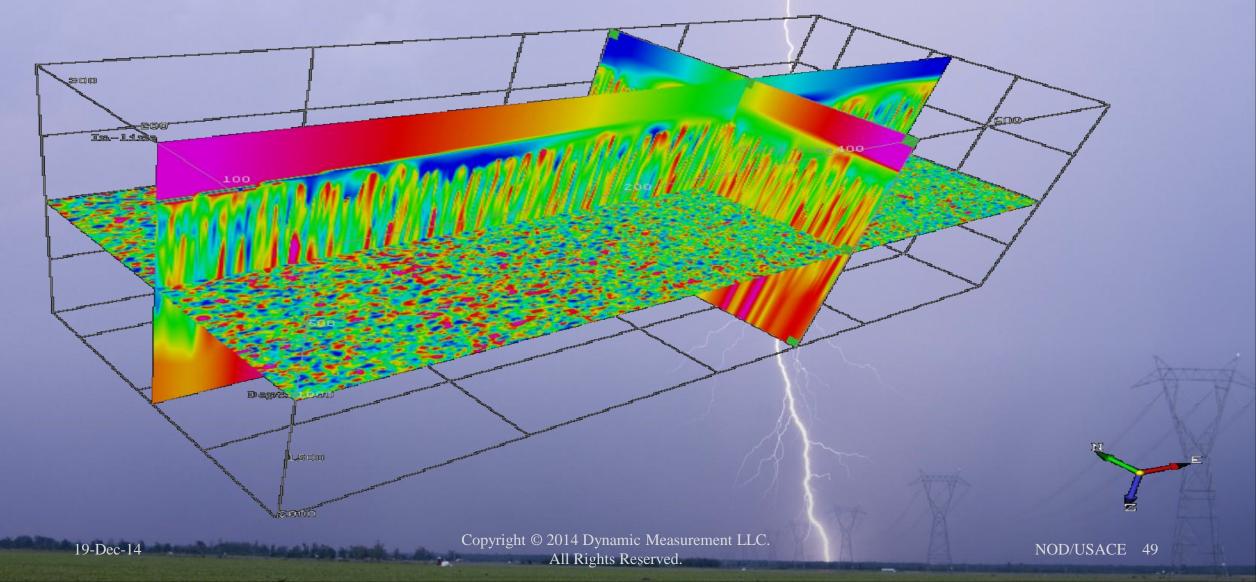

- For standard seismic interpretation software, data traces need to be uniformly sampled in time or depth, with the same number of samples in each trace
 - At latitude and longitude for the trace, each depth grid is sampled and each resistivity grid is sampled.
 - Resistivity values are interpolated with depth between these points to give samples at uniform intervals.
- Typical sample interval is 48 meters.
- Typical trace length is 125 samples.

A CONTRACTOR LOS AN A STATE

• There is no restriction in sample interval or length beyond those imposed by the SEG-Y format.
